### Introduction

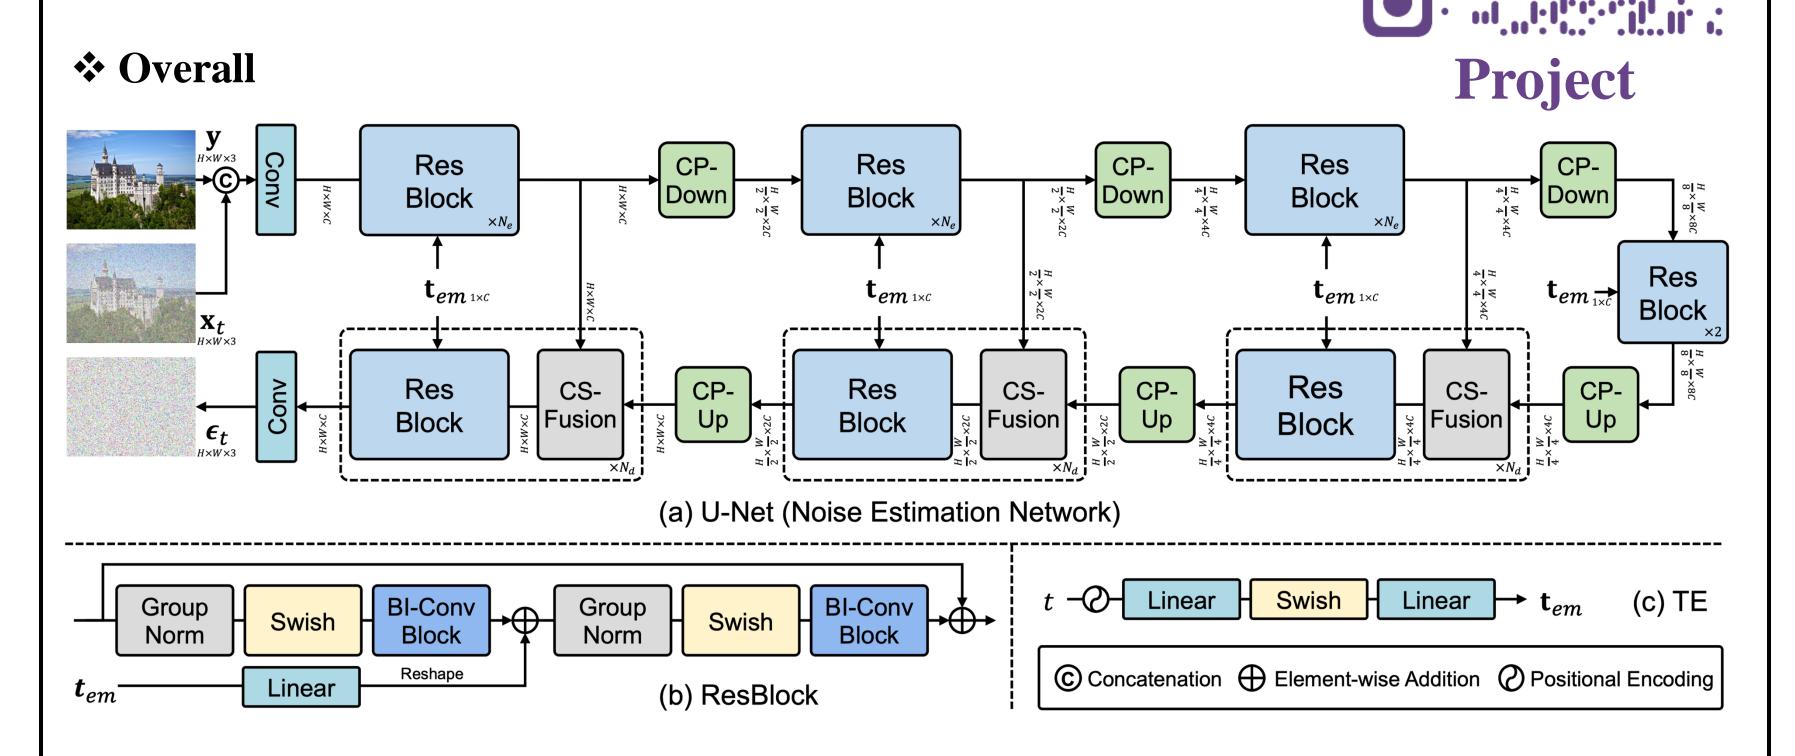

**Diffusion models (DMs)** excel in SR tasks but face high costs. **Binarization** (1-bit quantization) reduces memory and computation. However, the architecture and iterative design of DM limit its application. To tackle this, we propose **BI-DiffSR**, a novel binarized DM for SR.

### Contribution

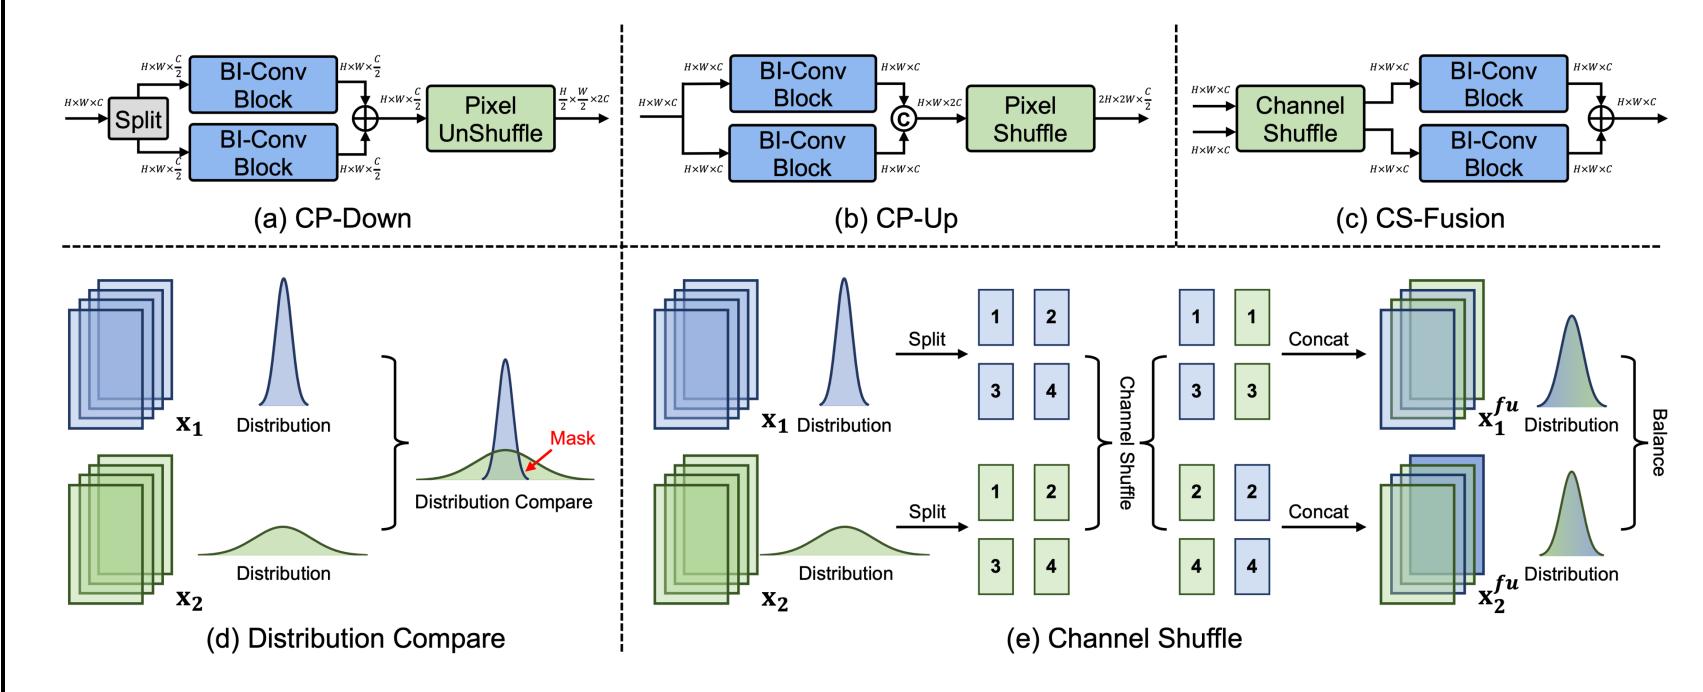

- Architecture: Design modules for binarization, including consistent-pixel-downsample (CP-Down) and upsample (CP-Up), and channel-shuffle-fusion (CS-Fusion).
- Activation: Introduce timestep-aware redistribution (TaR) and activation (TaA) to adapt activation distributions by timestep, enhancing binarized modules.
- **Performance:** Outperforms SOTA binarization methods and achieves perceptual quality comparable to full-precision models.

## Method

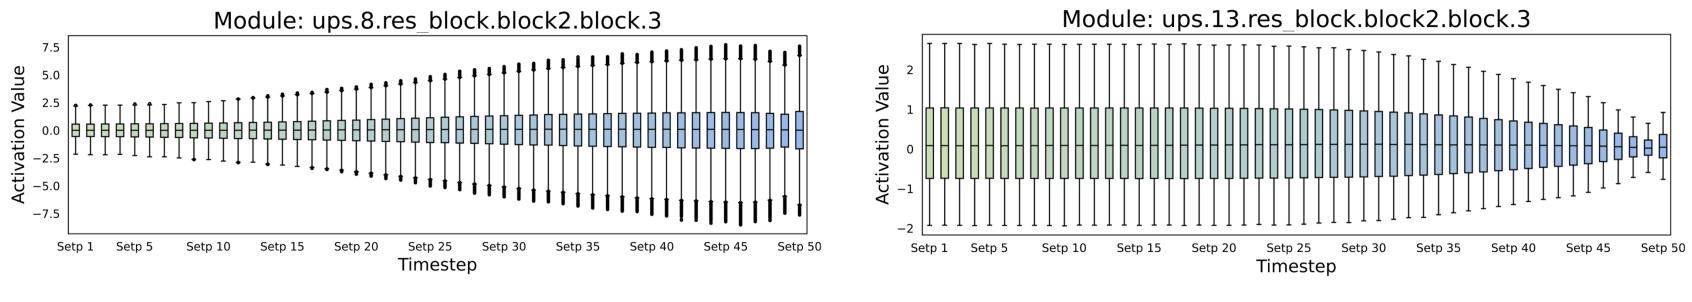

### **❖ Model Structure**

- Challenge I: Dimension Mismatch. Frequent changes in feature resolution cause dimension mismatches, blocking full-precision propagation.
- Challenge II: Fusion Difficulty. Significant activation range differences between the encoder and decoder hinder effective feature fusion in skip connections.

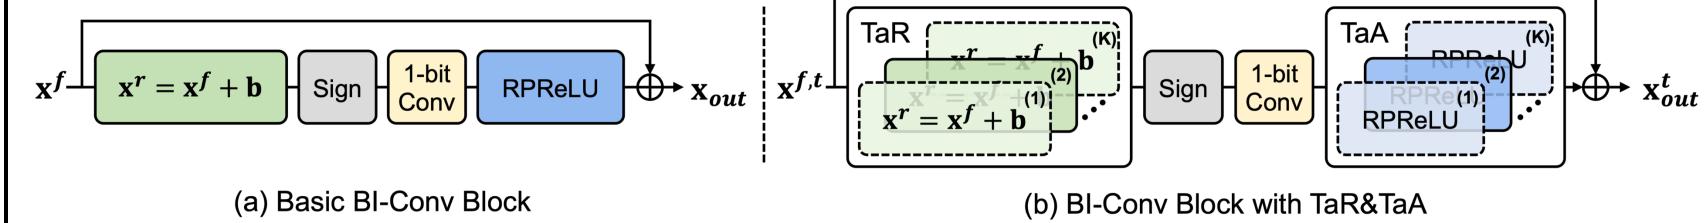

- **CP-Down/Up:** Ensures consistent feature reshaping, allowing identity shortcuts to maintain full-precision information transfer throughout the network effectively.
- **CS-Fusion:** Balances feature distribution by channel shuffle operation, ensuring better distribution matching and promoting more effective feature fusion.

### **Activation Distribution**

• Multi-step iterations in diffusion models change activation distributions, with adjacent timesteps appearing similar and distant ones differing significantly.

• TaR/TaA: Adjusts activations across timesteps, enhancing the binarized module.

# Experiments

### Ablation Study

thod	Baseline	+Identity	+CP-Down&Up	+CS-Fusion	+TaR&TaA	Method	Params (M)	OPs (G)	PSNR (dB)	LPIPS
